Calculating Area, Perimeter, and Length in ArcGIS

Written by Barbara M. Parmenter, revised 10/25/2011

You frequently need to calculate area, perimeter, or length for features in GIS. This can be accomplished using the Calculate Geometry function in an attribute table. Note you can also calculate the X and Y coordinates of a polygon or line centroid using this function. See ArcGIS 10 Help on for Calculating area, length, and other geometric properties for detailed information.

Important note: You can only calculate area, perimeter and length for projected data files! Data files that are in a geographic coordinate system, with units in decimal degrees (latitude and longitude) cannot have their area, perimeter and length calculated. You need to either project these data layers first, or set the Data Frame to a projected coordinate system. ESRI recommends that you use some kind of equal-area projection.

You also must have write permission to the data to calculate area, add a field, or do any other changes to table structure or values. That means you can’t do these operations on data stored on the Tufts M: drive – first copy the data to your own space.

Create a new attribute field to hold the area, perimeter, or length value

Typically you want to calculate area or perimeter or length for features that don’t already have an area field in the attribute table. To create a new attribute field to hold the area value, follow these steps.

1. Open the layer’s attribute table
2. Click on the Table Options icon in the top left corner of the table and choose Add Field
3. Name the new field (e.g., Acres) and make it *Double* type (numeric, double precision) and leave the precision and scale set to 0 and press OK.

To calculate area, perimeter, or length for a GIS data file

1. Open the layer’s attribute table, right-click on the name of the attribute field that will hold the area calculation (e.g., Acres) and choose *Calculate Geometry*

2. Ignore the warning message and press OK

3. Choose the property you want to calculate (e.g., Area), the coordinate system, and the units (e.g., acres), and press OK. *(Note: if you see that the fields are disabled - e.g., Area disabled – that means you are trying to calculate area for an unprojected data set. First set the Data Frame’s coordinate system to a projected coordinate system, then go through these steps again)*
4. Do the same for any other fields if necessary (length, perimeter)
